Readings for these lecture notes:

❑ **Probability & Statistics for Engineers & Scientists**,
Ninth edition, Ronald E. Walpole, Raymond H.
Myer

❑ **Elementary Statistics**, 10th Edition, Mario F. Triola

❑ **Probability Demystified**, Allan G. Bluman

These notes contain material from the above three books.

“Failure will never overtake me if my determination to succeed is strong enough.”

Og Mandino

Binomial Distribution [1]

A **binomial distribution** is obtained from a probability experiment called a binomial experiment. The experiment must satisfy these conditions:

1. Each trial can have only **two outcomes** or **outcomes that can be reduced to two outcomes**. The outcomes are usually considered as a success or a failure.
2. There is a **fixed number** of trials.
3. The outcomes of each trial are **independent** of each other.
4. The probability of a **success** must remain the **same** for each trial.

Binomial Distribution [3]

The binomial probability formula is used to compute **probabilities for binomial random** variables. The binomial probability formula is given as:

$$b(x; n, p) = c_x^n p^x q^{n-x}, x = 0, 1, 2, \dots$$

where $c_x^n = \frac{n!}{x!(n-x)!}$
OR

$$b(x; n, p) = \binom{n}{x} p^x q^{n-x}, x = 0, 1, 2, \dots$$

where n = the total number of trials

x = the number of successes (0, 1, 2, 3, . . . , n)

p = the probability of a success

q = the probability of a failure

Binomial Distribution [6]

□ The **normal distribution (Gaussian distribution)** can be regarded as the **limiting form** of the **binomial distribution** when n , the no. of trials is very large and neither p nor q is very small.

Note: Because the normal approximation is not accurate for small values of n , a good rule of thumb is to use the normal approximation only if **$np \geq 10$** and **$np(1-p) \geq 10$** .

The Mean and Standard Deviation for a Binomial Distribution [3]

EXAMPLE: Twelve cards are selected from a deck and each card is replaced before the next one is drawn. Find the average number of diamonds.

The Mean and Standard Deviation for a Binomial Distribution [4]

SOLUTION:

In this case, $n = 12$ and $p = \frac{13}{52}$

$$\text{Mean} = np = (12)\left(\frac{13}{52}\right)$$

$$\text{Mean} = 3$$

FIGURE 15.6 Examples of normal and skewed distributions

Reference:

<http://www.southalabama.edu/coe/bset/johnson/lectures/lec15.htm>

Positively Skewed Distribution

- In a positively skewed distribution:
- - Mean > Median > Mode
- This occurs because a few large values pull the mean to the right (higher values).

Negatively Skewed Distribution

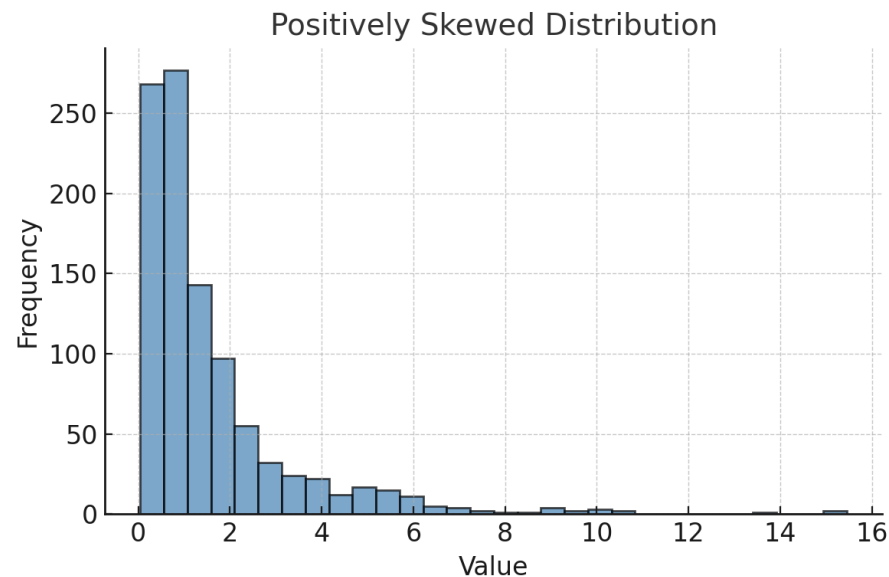

- In a negatively skewed distribution:
- - $\text{Mean} < \text{Median} < \text{Mode}$
- This occurs because a few small values pull the mean to the left (lower values).

Normal Distribution

- In a normal distribution:
- Mean = Median = Mode
- This indicates perfect symmetry, with data evenly distributed around the center.

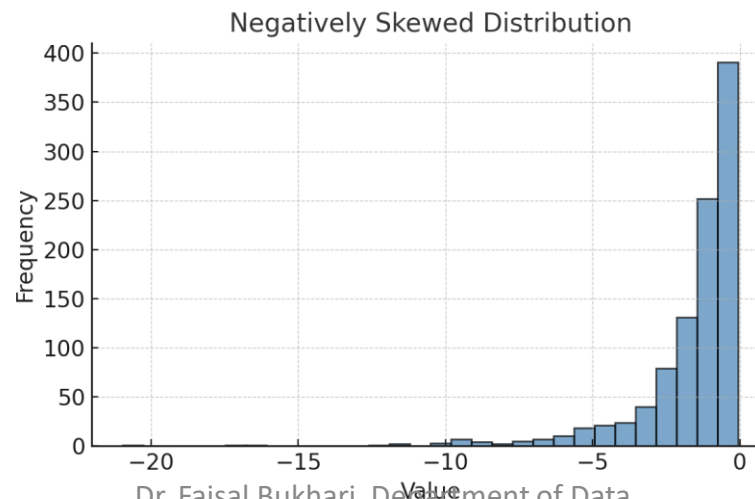

Positively Skewed Distribution

- A positively skewed distribution has most data concentrated on the left, with a few extreme values extending the tail to the right.
- Example: Income distribution, where a few people earn extremely high incomes.

Negatively Skewed Distribution

- A **negatively skewed distribution** has most data concentrated on the right, with a few extreme values extending the tail to the left.
- **Example:** Retirement age, where most people retire around a certain age, but a few retire much earlier.

Normal Distribution

- A **normal distribution** is symmetrical with the majority of the data concentrated around the mean, forming a bell-shaped curve.
- **Example:** Height distribution in a population, where most people are close to the average height.

The Mean and Standard Deviation for a Binomial Distribution [3]

EXAMPLE: A die is rolled 180 times. Find the standard deviation of the number of threes.

The Mean and Standard Deviation for a Binomial Distribution [4]

SOLUTION:

$$\text{Standard deviation} = \sqrt{npq}$$

$$\text{Standard deviation} = \sqrt{180\left(\frac{1}{6}\right)\left(\frac{5}{6}\right)}$$

The standard deviation is 5

What is the 3-Sigma Rule?

- The **3-sigma rule** (also known as the **Empirical Rule** or **68-95-99.7 Rule**) is a statistical rule that applies to normal distributions:
- **68%** of the data falls within **1 standard deviation (σ)** from the mean (μ).
- **95%** of the data falls within **2 standard deviations** from the mean.
- **99.7%** of the data falls within **3 standard deviations** from the mean.

Example 1: Height Distribution

- In a population of adult males with a mean height of 70 inches and a standard deviation (σ) of 3 inches:
- **68%** of men are between **67 and 73 inches tall**.
- **95%** of men are between **64 and 76 inches tall**.
- **99.7%** of men are between **61 and 79 inches tall**.
- Values **outside 61 and 79 inches** are considered rare (**outliers**).

Example 2: Manufacturing Quality Control

- In a process where metal rods have a mean diameter of 10mm and a standard deviation of 0.1mm:
- **68%** of rods have diameters between **9.9mm and 10.1mm**.
- **95%** of rods have diameters between **9.8mm and 10.2mm**.
- **99.7%** of rods have diameters between **9.7mm and 10.3mm**.
- Rods with diameters outside **9.7mm to 10.3mm are considered defects**.

Key Takeaways

- The **3-sigma rule** helps in identifying the **normal range of data in a normal distribution**.
- **Values outside** the 3-sigma range **are rare and considered outliers**.
- It is widely used in quality control, finance, and statistical analysis.

The Mean and Standard Deviation for a Binomial Distribution [5]

Roughly speaking, most of the values fall within two standard deviations of the mean.

$$\mu - 2\sigma < \text{most values} < \mu + 2\sigma$$

In the die example, we can expect most values will fall between

$$30 - 2 \times 5 < \text{most values} < 30 + 2 \times 5$$

$$20 < \text{most values} < 40$$

The Mean and Standard Deviation for a Binomial Distribution [6]

EXAMPLE: An archer hits the bull's eye **80%** of the time. If he shoots **100** arrows, find the mean and standard deviation of the number of bull's eyes. If he travels to many tournaments, find the approximate range of values.

The Mean and Standard Deviation for a Binomial Distribution [6]

SOLUTION:

$$n = 100, p = 0.80, q = 1 - p = 1 - 0.80 = 0.20$$

$$\text{Mean} = \mu = np = 100 \times 0.80 = 80$$

$$\begin{aligned}\text{Standard Deviation} = \sigma &= \sqrt{npq} \\ &= \sqrt{100 \times 0.80 \times 0.20} = 4\end{aligned}$$

$$\mu - 2\sigma < \text{most values} < \mu + 2\sigma$$

$$80 - 8 < \text{most values} < 80 + 8$$

$$72 < \text{most values} < 88$$

Example: The probability that a certain kind of component will survive a shock test is $\frac{3}{4}$. Find the probability that exactly **2** of the **next 4** components tested survive.

Solution:

Here $n = 4$

$$p = \frac{3}{4} \quad \text{(probability of survive a shock test)}$$

$$\because p + q = 1$$

$$q = 1 - p = 1 - \frac{3}{4} = \frac{1}{4}$$

Let x denotes number of components that survive a shock test

$$b(x; n, p) = \binom{n}{x} p^x q^{n-x}, x = 0, 1, 2, 3, \dots, n$$

$$b\left(2; 4, \frac{3}{4}\right) = \binom{4}{2} \left(\frac{3}{4}\right)^2 \left(\frac{1}{4}\right)^{4-2} = \frac{27}{128} = 0.2109$$

Binomial Distribution [1]

EXAMPLE 1: The probability that a patient recovers from a rare blood disease is **0.4**. If **15** people are known to have contracted this disease, what is the probability that

- (a) at least 10 survive
- (b) from 3 to 8 survive
- (c) exactly 5 survive

SOLUTION

$$(a) P(X \geq 10) = 1 - P(X < 10) = 1 - \sum_{x=0}^{x=9} b(x; 15, 0.4) = 1 - .9662 = 0.033$$

$$(b) P(3 \leq X \leq 8) = \sum_{x=3}^{x=8} b(x; 15, 0.4) \\ = \sum_{x=0}^{x=8} b(x; 15, 0.4) - \sum_{x=0}^{x=2} b(x; 15, 0.4)$$

(By using Table A.1 of the Appendix for $n = 1, 2, \dots, 20$, and selected values of p ; from 0.1 to 0.9)

$$= .9050 - 0.0271 = 0.8779$$

Binomial Distribution [2]

$$\begin{aligned} \text{(c) } P(X = 5) &= \sum_{x=0}^5 b(x; 15, 0.4) - \sum_{x=0}^4 b(x; 15, 0.4) \\ &= 0.4032 - 0.2173 = 0.1859 \end{aligned}$$

(By using Table A.1 of the Appendix for $n = 1, 2, \dots, 20$, and selected values of p ; from 0.1 to 0.9)

Conjectured: Opinion or judgment based on inconclusive or incomplete evidence; guesswork

Or

An opinion or conclusion based on guesswork.

The commentators made various conjectures about the outcome of the next election.

Binomial Distribution [3]

It is conjectured that an impurity exists in **30%** of all **drinking wells** in a certain **rural community**. In order to gain some insight into the true extent of the problem, it is determined that **some testing is necessary**. It is too expensive to test all of the wells in the area, so **10** are randomly selected for testing.

(a) Using the binomial distribution, what is the probability that exactly **3 wells** have the impurity, assuming that the **conjecture is correct**?

(b) What is the probability that **more than 3 wells** are impure?

Solution :

$$\begin{aligned} \text{(a) } b(3; 10, 0.3) &= \sum_{x=0}^3 b(x; 10, 0.3) - \\ &\quad \sum_{x=0}^2 b(x; 10, 0.3) \\ &= 0.6496 - 0.3828 = \mathbf{0.2668} \end{aligned}$$

$$\begin{aligned} \text{(b) } P(X > 3) &= 1 - P(X \leq 3) \\ &= 1 - \sum_{x=0}^3 b(x; 10, 0.3) \\ &= 1 - 0.6496 = \mathbf{0.3504} \end{aligned}$$

Binomial Distribution [3]

Example : Consider the situation of the previous example. The "**30% are impure**" is merely a conjecture put forth by the area water board. Suppose **10 wells** are randomly selected and **6 are** found to contain the impurity. What does this imply about the conjecture? Use a probability statement.

Solution: We must first ask: “If the conjecture is correct, is it likely that we could have found 6 or more impure wells?”

$$P(X \geq 6) = 1 - P(X < 6) = \sum_{x=0}^{10} b(x; 10, 0.3) - \sum_{x=0}^5 b(x; 10, 0.3)$$

$$= 1 - 0.9527 = 0.0473 \text{ or } \mathbf{4.7\%}$$

- ❑ As a result, it is very unlikely (**4.7% chance**) that **6 or more wells** would be found impure if only **30%** of all are impure.
- ❑ This casts considerable doubt on the conjecture and suggests that the **impurity problem** is much **more severe**.

Binomial Distribution [4]

Example : A family has 6 children. Find the probability P that there are

- (i) 3 boys and 3 girls.
- (ii) fewer boys than girls.

Assume that the probability of any particular child being a boy is $1/2$.

Solution:

Here $n = 6$ and $p = q = 1/2$.

Let X denotes number of boys

$$(i) \quad P(X = 3) = {}_6C_3(1/2)^3(1/2)^3 = 20/64 = \mathbf{5/16 = 0.3125 (31.25\%)}$$

(ii) There are fewer boys than girls if there are 0, 1 or 2 boys.

$$\begin{aligned} P(X \leq 2) &= {}_6C_0(1/2)^0(1/2)^6 + {}_6C_1(1/2)^1(1/2)^5 + \\ &{}_6C_2(1/2)^2(1/2)^4 \\ &= \mathbf{11/32 = 0.3438 (34.38\%)} \end{aligned}$$

Example Jury Selection In the case of *Castaneda v. Partida* it was noted that although **80%** of the population in a **Texas county** is **Mexican-American**, only **39%** of those summoned for grand juries were **Mexican-American**. Let's assume that we need to select **12 jurors** from a population that is **80% Mexican-American**, and we want to find the probability that among **12 randomly** selected jurors, exactly **7** are **Mexican-Americans**.

a. Does this procedure result in a **binomial distribution**?

b. If this procedure does result in a binomial distribution, identify the values of **n , x , p , and q** .

Solution a.

1. The number of **trials (12)** is **fixed**.
2. The **12 trials** are **independent**. (Technically, the 12 trials involve selection **without replacement** and are not independent, but we can assume independence because we are randomly selecting only 12 members from a very large population.)
3. Each of the **12 trials** has **two categories of outcomes**: The juror selected is either **Mexican-American** or is **not**.
4. For each **juror selected**, the probability that he or she is **Mexican-American** is **0.8** (because 80% of this population is Mexican-American). That probability of **0.8 remains** the same for each of the **12 jurors**.

b. Having concluded that the given procedure does result in a binomial distribution, we now proceed to identify the values of **n , x , p , and q** .

- 1.** With **12 jurors** selected, we have **$n = 12$** .
- 2.** We want the probability of exactly **7 Mexican-Americans**, so $x = 7$.
- 3.** The probability of success (getting a Mexican-American) for one selection is 0.8, so **$p = 0.8$** .
- 4.** The probability of failure (not getting a Mexican-American) is **0.2**, so $q = 0.2$.

Applications of Binomial Distribution in CS & ML

1. **Binary Classification** (Spam vs Non-spam emails)
2. **A/B Testing** (UI designs comparison)
3. **Error Detection** in Communication Systems
4. **Feature Selection** in Machine Learning
5. **Bagging in Ensemble Methods** (Random Forests)
6. **Click-Through Rate** Prediction
7. **Testing Hypotheses** in Learning Algorithms

Detailed Example: Binary Classification

- **Scenario:** Classifying emails as spam or non-spam.
- Each **email has a probability (p)** of being correctly classified.
- Use binomial distribution **$b(n, p)$** where **n is the number of emails.**
- Helps in estimating the number of **correctly classified emails.**

Detailed Example: A/B Testing

- **Scenario:** Testing two versions of a system (e.g., UI designs).
- Each user has a **probability (p)** of preferring version A.
- Use **binomial distribution $b(n, p)$** where n is the number of users.
- Helps in determining the significance of the test results.

Detailed Example: Bagging in Random Forests

- **Scenario:** Combining predictions from multiple models.
- Each model has a **probability (p)** of making the correct prediction.
- Use **binomial distribution $b(n, p)$** where n is the number of models.
- Helps in assessing the performance of the ensemble model.
